Introduction

To quote directly from the [data source itself](#):

The dataset contains 9568 data points collected from a Combined Cycle Power Plant over 6 years (2006-2011), when the power plant was set to work with full load. Features consist of hourly average ambient variables Temperature (T), Ambient Pressure (AP), Relative Humidity (RH) and Exhaust Vacuum (V) to predict the net hourly electrical energy output (EP) of the plant.

A combined cycle power plant (CCPP) is composed of gas turbines (GT), steam turbines (ST) and heat recovery steam generators. In a CCPP, the electricity is generated by gas and steam turbines, which are combined in one cycle, and is transferred from one turbine to another. While the Vacuum is collected from and has an effect on the Steam Turbine, the other three of the ambient variables effect the GT performance.

In this project, I will try to develop predictive models for this dataset. I will start with linear regression and see what other models can bring.

Data Preparation

The first thing to do was convert the .ods file into a .csv file using LibreOffice. The data.csv file is the result, and has been loaded:

```
# Init
library(e1071)
library(caret)

## Loading required package: lattice
## Loading required package: ggplot2

library(corrplot)
library(ggplot2)
library(GGally)
library(forecast)
```

```

## Loading required package: zoo
##
## Attaching package: 'zoo'
##
## The following objects are masked from 'package:base':
##   as.Date, as.Date.numeric
##
## Loading required package: timeDate
##
## Attaching package: 'timeDate'
##
## The following objects are masked from 'package:e1071':
##   kurtosis, skewness
##
## This is forecast 6.1

# Load data
df <- read.csv("CCPP/data.csv")
predictors <- c("V", "AT", "RH", "AP")
#df.predictors <- df[, c("V", "AT", "RH", "AP")]
#df.predict <- data.frame(PE=df[, c("PE")])

```

Lets see if there are any non-complete cases in the data:

```

sum(complete.cases(df$AT)) == nrow(df) # True
sum(complete.cases(df$V)) == nrow(df) # True
sum(complete.cases(df$AP)) == nrow(df) # True
sum(complete.cases(df$RH)) == nrow(df) # True

```

It looks like we have a full data set with no missing NA values. Lets see if any of the predictors are significantly skewed:

```

skewValues <- apply(df[, predictors], 2, skewness)
head(skewValues)

```

```

##          V          AT          RH          AP
##  0.1984588 -0.1363503 -0.4317034  0.2653615

```

From this I would say that there is no significant skewness here, so Box Cox transformations are not needed.

TODO: * should we transform via center and scaling?

Lets remove any near zero variance predictors:

```

remove <- nearZeroVar(df[, predictors]) # No columns are near zero variance

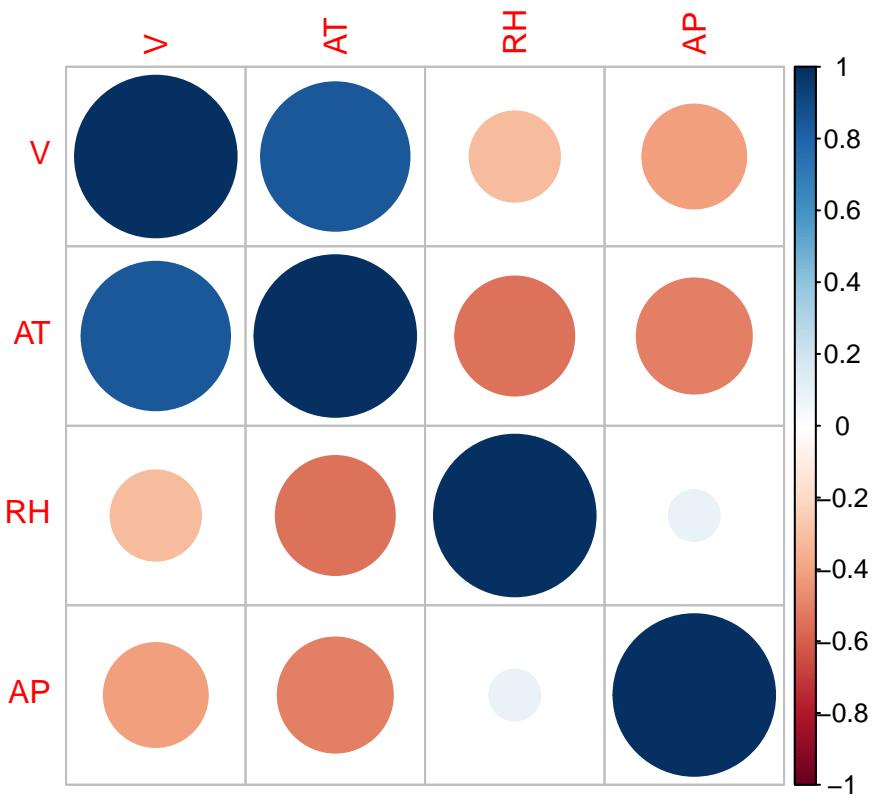

```

Are there any correlations between predictors?

```

correlations <- cor(df[, predictors])
corrplot::corrplot(correlations, order = "hclust")

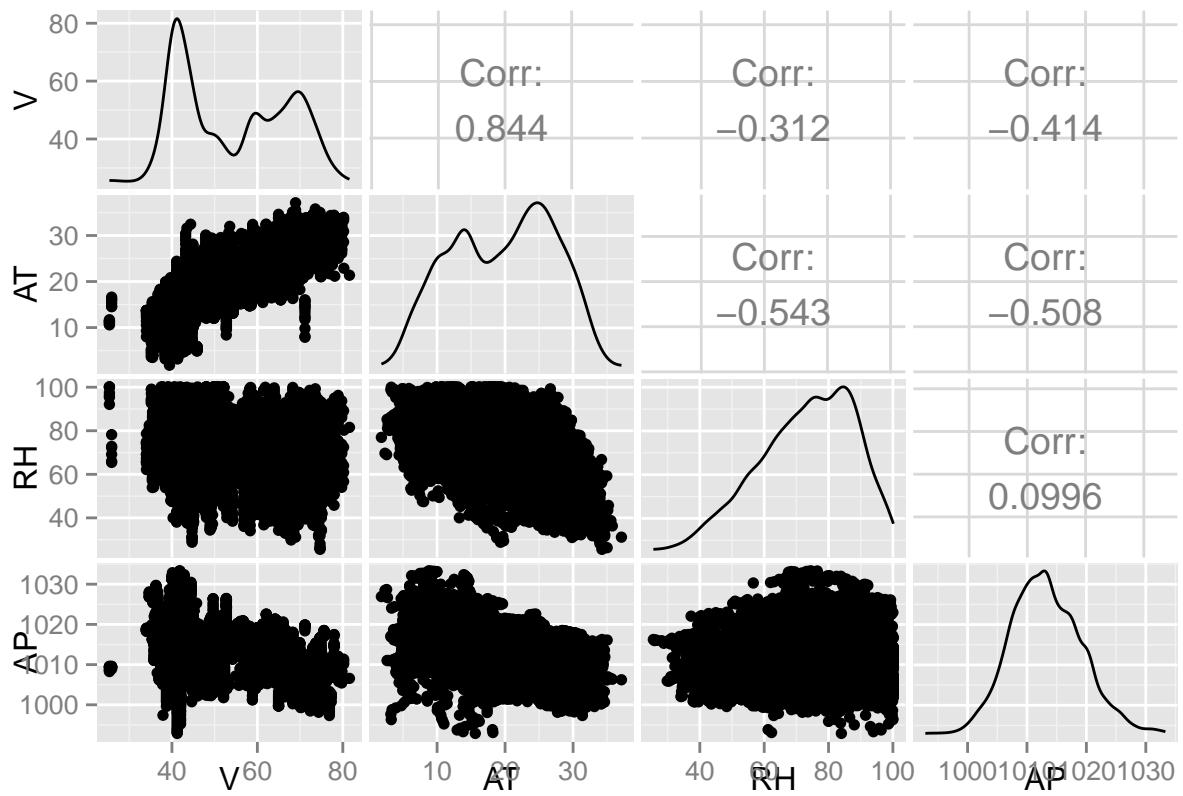

```

From this we can see some correlations between predictors, but that might be normal: the operating conditions of the plant probably change according to fundamental physical laws and operating constraints, so their changes over time might be correlated.

Lets view that data:

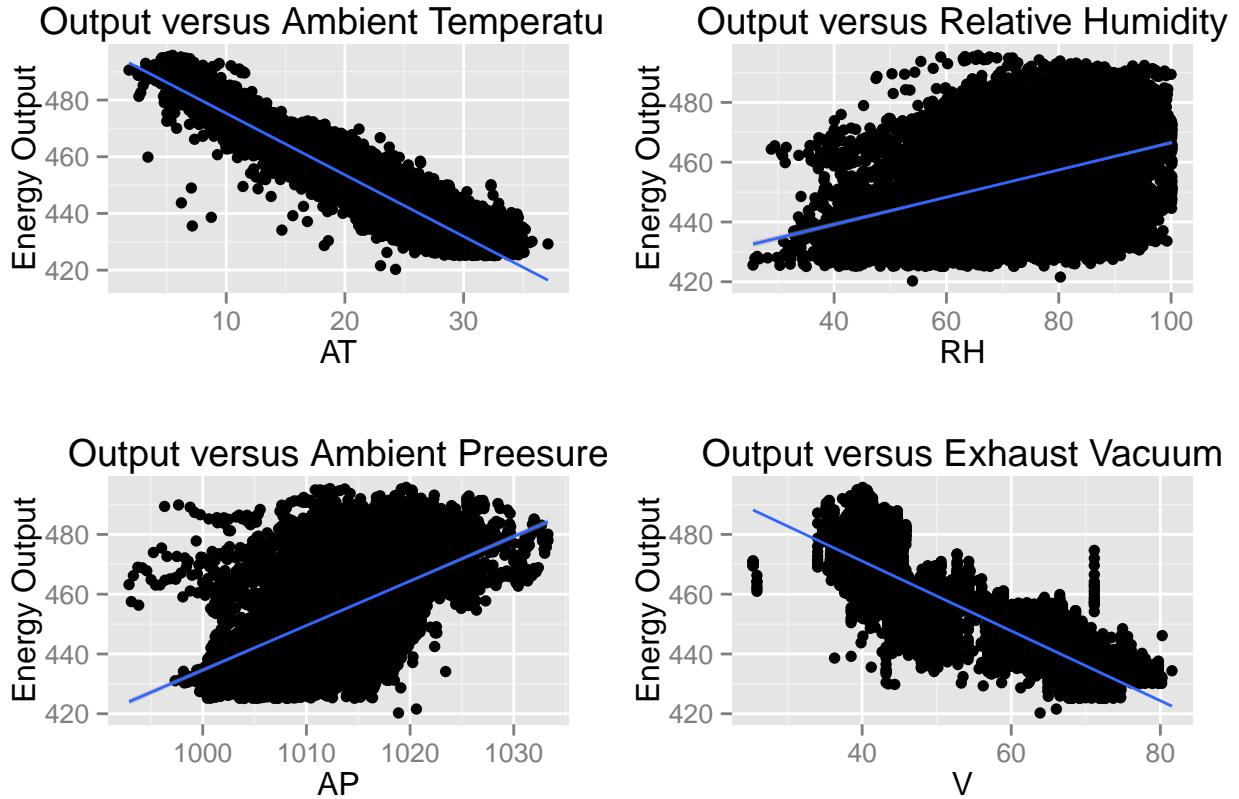

```
ggpairs(df[ , predictors])
```

```

p1 <- ggplot(df, aes(x=AT, y=PE)) + geom_point() + geom_smooth(method='lm') + ggtitle("Output versus Am")
p2 <- ggplot(df, aes(x=AP, y=PE)) + geom_point() + geom_smooth(method='lm') + ggtitle("Output versus Am")
p3 <- ggplot(df, aes(x=RH, y=PE)) + geom_point() + geom_smooth(method='lm') + ggtitle("Output versus Re")
p4 <- ggplot(df, aes(x=V, y=PE)) + geom_point() + geom_smooth(method='lm') + ggtitle("Output versus Exh")
multiplot(p1, p2, p3, p4, cols=2)

```

For the next steps, where we build models for this data, lets create a training and test set for performance measures:

```
trainIndex <- createDataPartition(df$PE, p = .8, list=FALSE)
df.training <- df[trainIndex, ]
df.test <- df[-trainIndex, ]
```

Linear Regression Model

```
# Build Lineat Regression Model
fit <- lm(PE ~ V + AT + RH + AP, data=df.training)
summary(fit)

##
## Call:
## lm(formula = PE ~ V + AT + RH + AP, data = df.training)
##
## Residuals:
##      Min       1Q   Median       3Q      Max 
## -42.997  -3.157  -0.135   3.200  17.819 
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)    
## (Intercept) 453.890613  10.811762  41.981 < 2e-16 ***
## V          -0.239238   0.008082 -29.600 < 2e-16 ***
## AT         -1.972589   0.017013 -115.947 < 2e-16 ***
```

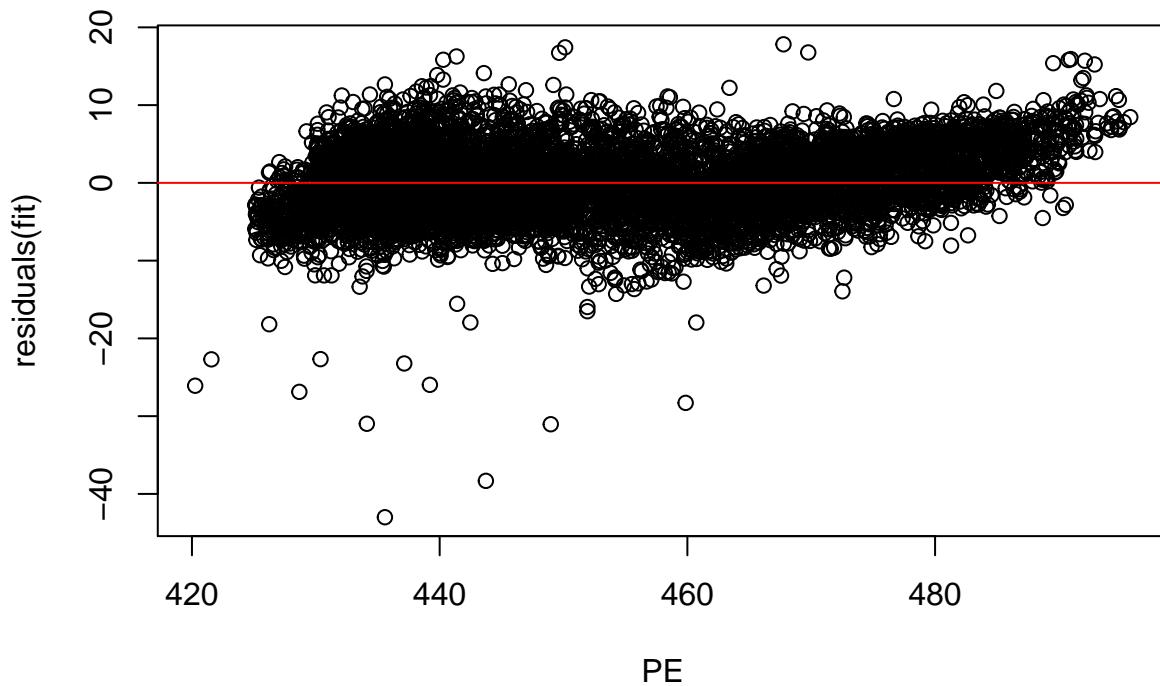

```

## RH          -0.158495   0.004647  -34.109 < 2e-16 ***
## AP           0.062975   0.010489     6.004 2.02e-09 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 4.534 on 7651 degrees of freedom
## Multiple R-squared:  0.9296, Adjusted R-squared:  0.9295
## F-statistic: 2.525e+04 on 4 and 7651 DF, p-value: < 2.2e-16

# Residuals
plot(residuals(fit) ~ PE, data=df.training, main="Residuals Plot")
abline(0, 0, col='red')

```

Residuals Plot

```

# Forecast the data
forecast <- forecast(fit, newdata=df.test)
accuracy(forecast, df.test)

##               ME      RMSE      MAE      MPE      MAPE
## Training set 6.903615e-17 4.532282 3.608968 -0.009686745 0.7959303
